Abstract

C. difficile infection among people traditionally not considered high risk, such as younger and healthy individuals without a history of antibiotic use or exposure to health care facilities. Each year in the United States, about a half million people get sick from *C. difficile*, and in recent years, *C. difficile* infections have become more frequent, severe and difficult to treat. Toxin B (TcdB) is a cytotoxin that has a molecular weight of 270 kDa and an isoelectric point, pl, of 4.1. Toxin B has four different structural domains: catalytic, cysteine protease, translocation, and receptor binding. The sequence analysis of Toxin B protein retrieved from [NCBI] in fasta format. The structural analysis of Toxin B was carried out by using bioinformatics tools, like ncbi, pdb, amigo, drug bank, clustal w, online smiles translator.

Keywords

C. difficile, cytotoxin, Toxin B, NCBI, pdb , amigo, drug bank, clustal w.

INTRODUCTION

Clostridium difficile (kilos-TRID-e-um dif-uh-SEEL), often called *C. difficile* or *C. diff*, is a bacterium that can cause symptoms ranging from diarrhea to life-threatening inflammation of the colon. Illness from *C. difficile* most commonly affects older adults in hospitals or in long-term care facilities and typically occurs after use of antibiotic medications. However, studies show increasing rates of *C. difficile* infection among people traditionally not considered high risk, such as younger and healthy individuals without a history of antibiotic use or exposure to health care facilities. Each year in the United States, about a half million people get sick from *C. difficile*, and in recent years, *C. difficile* infections have become more frequent, severe and difficult to treat. *C. difficile* bacteria are found throughout the environment — in soil, air, water, human and animal feces, and food

products, such as processed meats. A small number of healthy people naturally carry the bacteria in their large intestine and don't have ill effects from the infection. *C. difficile* infection is most commonly associated with health care and recent antibiotic use, occurring in hospitals and other health care facilities where a much higher percentage of people carry the bacteria. However, studies show increasing rates of community-associated *C. difficile* infection, which occurs among populations traditionally not considered high risk, such as children and people without a history of antibiotic use or recent hospitalization. Spores from *C. difficile* bacteria are passed in feces and spread to food, surfaces and objects when people who are infected don't wash their hands thoroughly. These spores can persist in a room for weeks or months. If you touch a surface contaminated with *C. difficile* spores, you may then unknowingly swallow the

bacteria. Your intestines contain about 100 trillion bacterial cells and up to 2,000 different kinds of bacteria, many of which help protect your body from infection. When you take an antibiotic to treat an infection, these drugs tend to destroy some of the normal, helpful bacteria in addition to the bacteria causing the infection. Without enough healthy bacteria to keep it in check, *C. difficile* can quickly grow out of control. The antibiotics that most often lead to *C. difficile* infections include fluoroquinolones, cephalosporins, penicillins and clindamycin. Once established, *C. difficile* can produce toxins that attack the lining of the intestine. The toxins destroy cells and produce patches (plaques) of inflammatory cells and decaying cellular debris inside the colon and cause watery diarrhea.

METHODOLOGY

Target protein of Toxin B in *Clostridium difficile* were retrieved from NCBI database. The sequence is submitted to PDB database for similarity search of Toxin B. The retrieved sequence is submitted to the amigo server for annotation analysis of Toxin B protein. The retrieved sequence is submitted to the JCAT server for gene expression analysis of annotated sequence with Toxin B proteins. The retrieved sequence is submitted to the Clustal-W server for multiple sequence alignment of annotated sequence with Toxin B protein. The retrieved sequence is submitted to bioedit server for sequence analysis of Toxin B protein. Based upon the bioavailability of drug ,drug compound were selected and drug like properties of the selected compound were analyzed using tools like online smiles translator and molinspiration server.

CONCLUSION

The main source of transmission is patients with symptomatic infection. These people shed large numbers of *C. difficile* spores and bacteria in the feces, resulting in widespread contamination of their skin, bed linen and nearby environmental surfaces. The spores are resistant to drying and the usual chemical cleaning agents and can therefore remain in the environment for weeks or months. Spores can then be picked up on the hands of patients and healthcare workers. The glycosylation activity of toxin B occurs in the N-terminal catalytic region (residues 1–544). This region glycosylates substrates independent of any cytotoxic activity.[6] However, a small deletion of the receptor binding region causes attenuation of toxin B activity.[6] The translocation region contains a hydrophobic stalk-like structure, which may help residues 958–1130 in forming membrane spanning pores. The sequence of Toxin B protein retrieved from NCBI database in fasta format. The Sequential analysis of Toxin B protein were carried out by using bioinformatic tools, like NCBI, pdb, amigo, Clustal w. In future toxin B will have more application in the field of pharmacology.
